## Comparison of Different Whole Blood Sample Pretreatment Methods for Targeted Analysis of Basic Drugs

Seyed Sadjadi, Shahana Huq, Sean Orłowicz, and Laura Snow  
Phenomenex, Inc., 411 Madrid Avenue, Torrance, CA 90501 USA

### Introduction

Drug analysis from whole blood is a challenge due to the complex matrix and the presence of erythrocytes, the concentration of which can vary from sample to sample.

Any drug analysis in whole blood generally requires some form of a pretreatment procedure that simplifies the blood matrix before the actual analyte extraction. However, many procedures can efficiently be applied to hemolyze the erythrocytes. Likewise, there are equally many capable methods to precipitate the plasma proteins. Ultimately, a successful pretreatment method should produce a high degree of recovery for all analytes in the sample.

Here, we evaluated several common pretreatment procedures<sup>1,2</sup> that both lyse the cells and precipitate the plasma proteins. These include acidic reagents (10% TCA and 6% HClO<sub>4</sub>), organic solvent mixtures (MeOH and ACN) and a combination of zinc sulfate and an organic solvent (**Table 2**). Subsequently, the clarified supernatant was processed through a polymeric cation-exchange solid phase extraction (SPE) tube (Strata<sup>®</sup>-X-C) to extract the basic drugs. The list of the class of compounds that were targeted for this work includes amphetamines (amphetamine, methamphetamine, MDA, MDEA, etc), natural and synthetic opiates (morphine, codeine, hydromorphone, hydrocodone, etc) illicit drugs (PCP, benzoylecgonine), benzodiazepines (alprazolam, lorazepam, etc) and analgesics (tramadol) (**Table 1**).

After the initial evaluation, we constructed a calibration curve using whole blood as a matrix. Replicate analysis of 20 and 200 ng/mL spiked whole blood samples were used for the precision and accuracy study.

**Table 1.** List of pain panel drugs

Class	Analyte	Class	Analyte
Benzodiazepines	Alprazolam	Synthetic Opioids	Methadone
	Clonazepam		EDDP
	Diazepam		Fentanyl
	Flunitrazepam		Norfentanyl
	Lorazepam		Meperidine
	Midazolam		Normeperidine
	Nordiazepam		Naloxone
	Oxazepam		Norpropoxyphene
	Temazepam		Propoxyphene
	$\alpha$ -Hydroxyalprazolam		Sufentanil
Opiates	Alprazolam	Amphetamines	Naltrexone
	Codeine		Amphetamine
	Hydrocodone		Methamphetamine
	Hydromorphone		MDMA
	Morphine		MDA
	6-Acetylmorphine (6-MAM)		MDEA
Illicit Drugs	Oxymorphone	Analgesics	Tramadol
	Phencyclidine		Carisoprodol
	Benzoylecgonine		Buprenorphine
			Norbuprenorphine

**Table 2.** Evaluated pretreatment methods

Acidic Reagents	10% TCA
	6% HClO <sub>4</sub>
Organic Solvents	90:10 ACN:MeOH
	50:50 ACN:MeOH
	10:90 ACN:MeOH
	100% MeOH
	100% ACN
Organic Solvent + ZnSO <sub>4</sub>	100% ACN
	90:10 ACN:MeOH
	100% MeOH

## Final Sample Preparation Method

### Pretreatment:

- Add 0.5 mL whole blood (with EDTA preservative) into a glass tube
- Add 100  $\mu$ L 5 % (w/v)  $ZnSO_4$  and vortex 3-5 sec
- Add 1.5 mL of chilled ( $\sim 0^\circ C$ ) 90:10 ACN/MeOH while vortexing
- Centrifuge samples at 6000 rpm for 10 min and transfer supernatant
- To supernatant, add 4 mL of aqueous 0.1 % formic acid to acidify and dilute the mixture

### SPE Cartridge:

Strata<sup>®</sup>-X-C, 30 mg/3 mL (Part No. [8B-S029-TBJ](#)) equipped with an adapter cap (Part No. [AH0-7191](#)) and a 12 mL reservoir (Part No. [AH0-7003](#))

**Condition:** 1 mL Methanol  
**Equilibrate:** 1 mL Water  
**Wash 1:** 1 mL 0.1 % Formic acid in water  
**Wash 2:** 1 mL 30 % Methanol in water  
**Dry:** 3 to 4 mins at high vacuum ( $\sim 10^{-2}$  of Hg)  
**Elute:** 2x 500  $\mu$ L (2 aliquots of 500  $\mu$ L) Ethyl acetate/Isopropanol/Ammonium hydroxide (70:20:10)  
**Dry down:** Evaporate to dryness under nitrogen at 40-45  $^\circ C$   
**Reconstitute:** With 500  $\mu$ L of 85:15 (A/B) of LC mobile phase

## Final LC-MS Method

**Column:** Kinetex<sup>®</sup> 2.6  $\mu$ m Biphenyl  
**Dimensions:** 50 x 3.0 mm  
**Part No.:** [00B-4622-Y0](#)  
**Mobile Phase:** A: 0.1 % Formic acid in water  
 B: 0.1 % Formic acid in methanol  
**Gradient:**

Time (min)	B (%)
0.0	10
2.5	100
3.5	100
3.5	10
5.0	10

**Flow Rate:** 0.7 mL/min  
**Temperature:** Ambient  
**Detection:** MS/MS, API 4000<sup>™</sup> (SCIEX)  
**System:** Shimadzu<sup>®</sup> Nexera<sup>®</sup> UFLC with LC-30AD pumps  
**Injection:** 10  $\mu$ L

## Results and Discussion

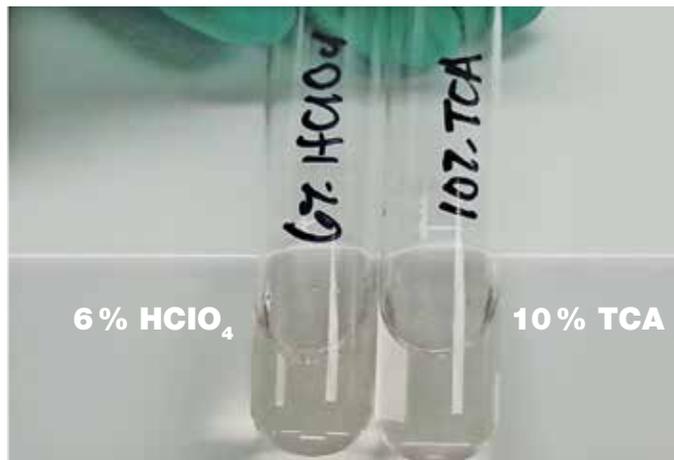

It appeared that not all pretreatment procedures produced the best results. In general, the acidic pretreatment methods produced the poorest overall responses despite a very clear pretreated sample (**Figures 1 and 5**), with some exceptions. This might be due to the hydrophobic nature of many of the compounds used here that are soluble (or stable) in the pretreated acidic solutions (**Figures 6 and 7**). Use of MeOH alone was not adequate to achieve a clear enough supernatant from whole blood. Acetonitrile with a small amount of MeOH produced better than expected recoveries for some classes of compounds such as opiates (**Figures 2 and 6**).

The pretreatment procedure with  $ZnSO_4$  and an organic solvent (acetonitrile or 90:10 ACN/MeOH) produced the most consistent results for many compounds (**Figure 3 and Table 3**).

### Figure 1. Acidic supernatant

#### Addition of Acidic Reagent

- Both 10 % trichloroacetic acid and 6 % perchloric acid produced very clear, colorless supernatants, even after dilution.

#### Key to Abbreviations:

$ZnSO_4$  = Zinc sulfate  
 $HClO_4$  = Perchloric acid  
 MeOH = Methanol  
 ACN = Acetonitrile  
 TCA = Trichloroacetic acid

**Figure 2.** Supernatant from organic solvents

Addition of Organic Solvents

- MeOH and/or mostly methanol solvent produced a supernatant with a slight hazy yellow tint
- Acetonitrile and/or mostly acetonitrile solvent produced a more clear and colorless supernatant. However, the supernatant turned cloudy when diluted.

**Supernatant**

(A)  
90:10 MeOH:ACN

(B)  
50:50 MeOH:ACN

(C)  
10:90 MeOH:ACN

**Supernatant post dilution**

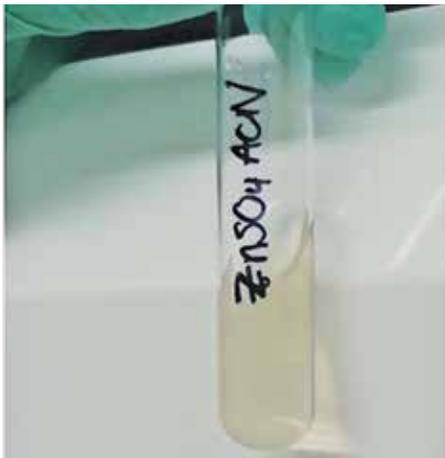

A B C

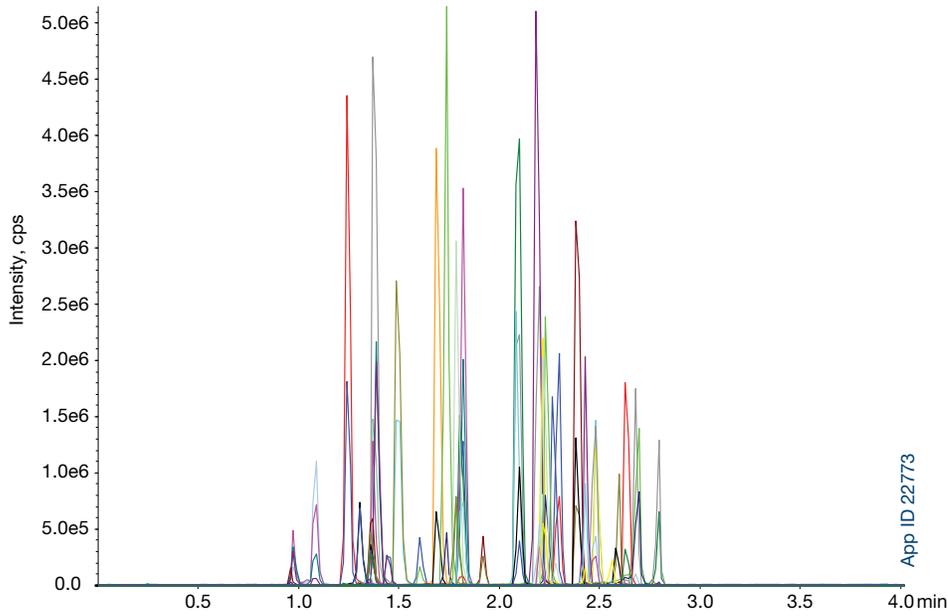

**Figure 3.** Supernatant from ZnSO<sub>4</sub> and ACN post dilution

Addition of ZnSO<sub>4</sub> and an Organic Solvent

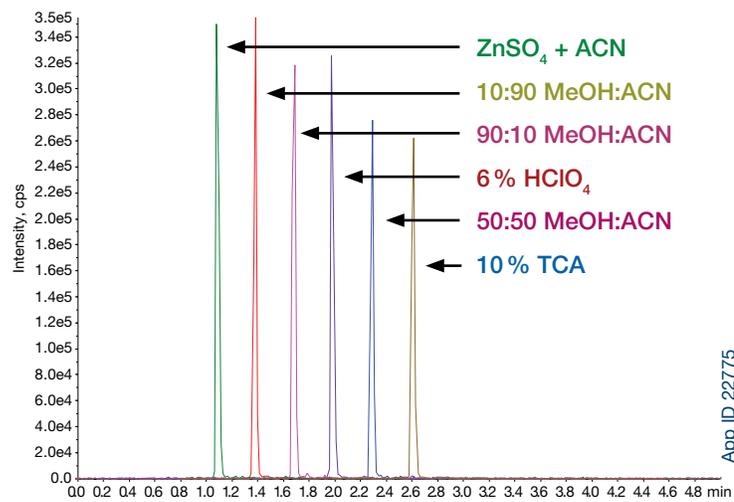

- When added to whole blood, zinc sulfate produced a bright red cloudy solution.
- Upon addition of the organic solvent, a brown precipitate appeared which lead to a clear and colorless supernatant.
- Upon dilution, the solution showed slight turbidity (ZnSO<sub>4</sub> and ACN supernatant is shown below).

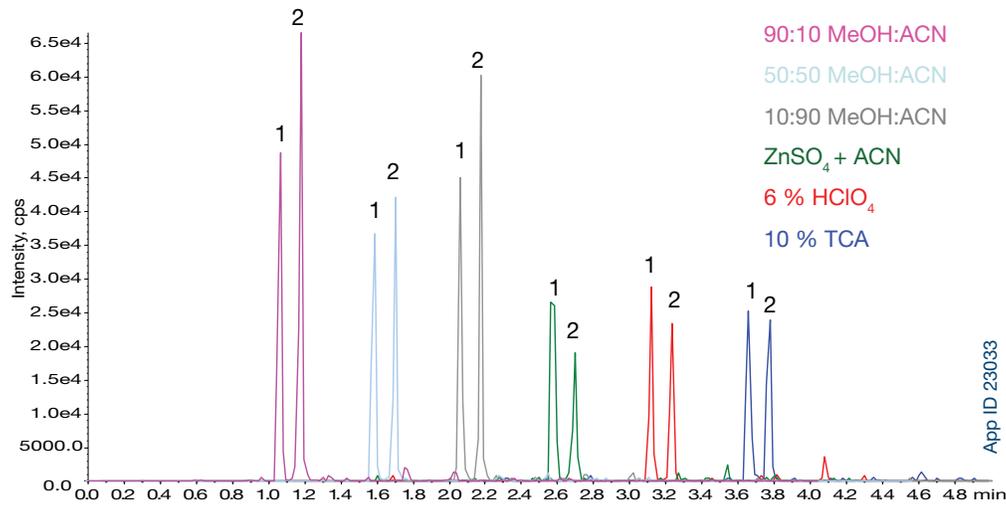

**Figure 4.** Representative chromatogram of the basic compounds

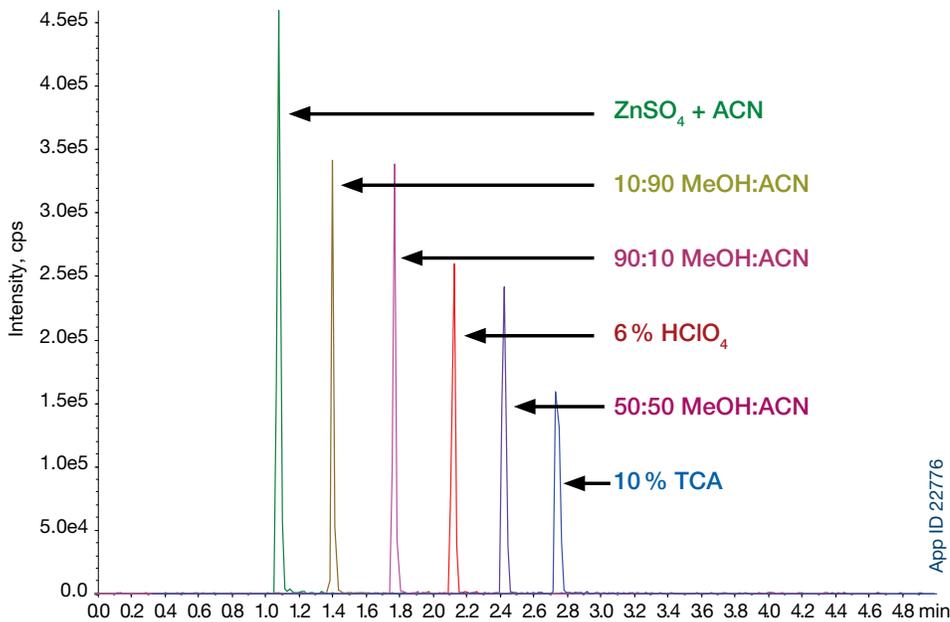

**Figure 5.** Comparison of the effects of various pretreatment options on amphetamine. Chromatograms are overlaid with time shift to provide clarity.

**Figure 6.** Comparison of the effects of various pretreatment options on Codeine (peak 1) and Hydrocodone (peak 2). Chromatograms are overlaid with time shift to provide clarity.

**Figure 7.** Comparison of the effects of various pretreatment options on Benzoylcegonine. Chromatograms are overlaid with time shift to provide clarity.

**Table 3.** Method Precision and Accuracy Data Based on Replicate Quality Control Samples

Analyte	Class	Expected Conc, ng/mL (Low)	%RSD (Low)	% Accuracy (Low)	Expected Conc, ng/mL (High)	%RSD (High)	% Accuracy (High)

## Conclusion

We have developed an effective pretreatment and SPE cleanup method for whole blood followed by targeted LC-MS/MS analysis. Zinc sulfate with an acetonitrile and methanol combination provided the best response for the majority of analytes tested. Further sample cleanup was successfully accomplished by using a cationic exchange SPE, Strata®-X-C, sorbent. This combination can greatly improve the column longevity and maintain a clean LC-MS/MS system. The combination of the pretreatment and SPE method can sufficiently be employed for a wide range of basic compounds generally encountered in existing pain panel methods.

## Acknowledgement

The authors are grateful for Mrs. Amanda Kaspick's gracious contributions and efforts to this project.
